| Sammendrag:<br><p>I forbindelse med Nordkalottprosjektet er det utført en begrenset geokjemisk prøvetaking i et 15 000 km<sup>2</sup> område omkring Treriks-røysa. Med en prøvetetthet på 1 prøve pr. 30 km<sup>2</sup> er det fra hver prøvestasjon samlet inn 6 forskjellige prøvetyper: bekkersedimenter, bekkemose, bekketorv, bekkevann, humus og morene.</p> <p>Denne lavtetthets geokjemiske prøvetakingen har avdekket regionale geokjemiske mønstre og lokale anomalier. Det anbefales derfor at hele Nordkalotten prøvetas med samme tetthet.</p> |                                                                                                                                |                          |
| Nøkkelord                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Nordkalotten                                                                                                                   |                          |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Regional geokjemi                                                                                                              |                          |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                |                          |

## INNLEDNING

I "Nordisk råvare- og ressursutredning - en presisering av noen samarbeidsmuligheter" (NU A1977:14) foreslås det en del nordiske samarbeidsprosjekter innenfor fagfeltet geologisk forskning.

Etter behandling av forslagene i den nordiske embedsmannskomite under Nordisk Ministerråd (6.10.1978), prioriterte representanter for forvaltningen i de nordiske land (16.3.1979) prosjektet:

"Definering av malmførende formasjoner og strukturer på Nordkalotten ved hjelp av regionale geologiske, geofysiske, geokjemiske og fotogeologiske undersøkelser."

Nordkalotten defineres i denne sammenheng som arealene nord for 66°N. Prosjektet ble etablert våren 1980 og ventes avsluttet i 1986. De geologiske undersøkelser i Finland, Norge og Sverige (Geologiska Forskningsanstalten (GF), Norges geologiske undersøkelse (NGU) og Sveriges geologiska undersökning (SGU)) utgjør prosjektets arbeidspartnere. Grønlands Geologiske Undersøgelse (GGU) har status som observatør.

Prosjektet er delt opp i 5 underprosjekter (berggrunnsgeologi, dataregister, geofysikk, geokjemi og kvartærgeologi).

Prosjektgruppen for geokjemi har gjennomgått de geokjemiske data som tidligere er samlet inn på Nordkalotten (Uppsala 18.3.1980). Gjennomgangen viste:

- 1) De geokjemiske data som eksisterer i Finland, Norge og Sverige er meget uensartet. Såvel prøvetype som metoder for prøvetaking og analysering varierer fra land til land.

- 2) I alle tre land er de tidligere prøvetatte arealer på Nordkalotten relativt små.

Sammenstilling av eksisterende geokjemiske data syntes derfor uhensiktsmessig, og prosjektgruppen foreslo en ny geokjemisk prøvetakning over hele Nordkalotten. Før en slik prøvetakning eventuelt settes igang, bør det gjennomføres et forprosjekt.

Etter at prosjektgruppens forslag var drøftet ved de berørte institusjoner, ble forprosjektet etablert våren 1980. De innsamlede prøver ble analysert ved GF, NGU og SGU i løpet av høsten/vinteren 1980/81.

Denne rapport er en kortfattet framstilling av forprosjektets resultater og fremmer forslag til videre arbeid.

#### UNDERSØKELSESONOMRÅDE OG BAKGRUNNSDATA

Det prøvetatte areal er ca. 13 000 km<sup>2</sup> og ligger ved 3-riksrøysen med omtrent like store deler i hvert av de tre land, se Figur 2-1.

Et geologisk kart basert på publiserte og upubliserte data fra GF, NGU og SGU er sammenstilt av H. Skålvoll og B. Zwaan, se Figur 2-2. De viktigste enheter er:

Arkeisk\_gneissområde. Diorittiske til kvartsittiske gneisser er metamorfosert i amfibolittfacies med utbredt skifrihet og foliasjon. Mot vest finnes metabasiske soner. Aldersbestemmelser har gitt 2600 m.å.

Karelske\_suprakrustaler. Der er to NNW strykende belter med suprakrustalbergarter som omfatter kvartsitter, glimmerskifre og grønnsteiner.

Basiske og sure intrusjoner. Basiske og ultrabasiske ganger opptrer i gneissområdet. I grønnstensbeltene finnes intrusjoner av gabbro og ultrabasitt, og dessuten en ca. 1850 - 1890 m.å. gammel dioritt-granodioritt. Røde kalifeltspatgranitter intruderte i gneisser og grønnstein for ca. 1550 - 1650 m.å. siden.

Kaledonider. Det kaledonske skyvedekkekompleks (Reisadekkekomplekset) omfatter metamorfoserte kambro-silurske sedimenter og basiske vulkanitter samt Prekambriske gneissflak. Grensen mot grunnfjellet utgjøres av en skyvefront som hviler på en serie med autoktone senprekambriske til kambriske sedimenter.

Kjente mineraliseringer er tegnet inn på Figur 2-3. I prekambrium finnes Cu- og Au-mineraliseringer knyttet til grønnstensbeltene. Mo og U opptrer nær grønnsteners kontakt med granitt. Ni og Cr kjennes fra ultramafitter. Pb er funnet i fjellranden. I kaledonidene finnes strati-forme kisforekomster samt jern- og manganforekomster.

Et aeromagnetisk kart (Figur 2-4) er sammenstilt på grunnlag av arkivdata fra GF, NGU og SGU.

Et gravimetrisk kart (Figur 2-5) er basert på data fra GF og Norges geografiske oppmåling.

#### METODER

Det ble valgt en prøvetetthet på 1 prøvestasjon pr. 35 km<sup>2</sup>. Før prøvetaking ble prøvestasjonene (ialt 368) lagt ut på topografiske kart med mest mulig lik innbyrdes avstand, og i dreneringssystemer med størrelse ca. 10 km<sup>2</sup>.

### Feltmetoder

Fra hver stasjon ble det om mulig samlet inn 6 ulike prøvetyper:

- Morene. Prøven ble tatt fra ca. 0,50 m dyp (C-horisont).
- Bekkesedimenter (uorganiske). Prøvene ble våtsiktet i felt til -0,18 mm.
- Bekkevann. Prøven ble filtrert i felten (-0,45 micron) og surgjort med ultrapur  $\text{HNO}_3$ .
- Bekkemose (vattenmossa). Mose på blokk eller blotninger i bekkeleiet ble foretrukket, men om nødvendig ble prøver tatt fra bekkekanten. Prøvene ble vasket mest mulig fri for sedimenter i felten.
- Bekketorv. Prøven består av humus fra bekkeleie eller bekkekant.
- Humus. Jordprøve fra  $A_0$ -laget, dyp vanligvis 2-5 cm. Humusprøvene er foreløpig ikke analysert, men arkivert ved SGU.

Morene- og bekkevannprøver ble tatt i ett punkt. For de øvrige bekkeprøver ble minst 5 underprøver tatt langs 50 m av bekken og slått sammen til en analyseprøve. Hver humusprøve består av minst 10 underprøver tatt innenfor et  $100 \text{ m}^2$  areal rundt morene-prøven.

### Laboratoriemetoder

De innsamlede prøver ble sendt til GF, NGU, SGU og GGU etter følgende plan:

|     |                                      |
|-----|--------------------------------------|
| GF  | Morene og bekkesedimenter            |
| NGU | Bekkevann og bekkesedimenter         |
| SGU | Bekkemose, bekketorv, humus          |
| GGU | Utvalgte vannprøver for uran-analyse |

Morene (-0,06 mm) ble analysert ved direkte opptak i kvantometer med tapemaskin. Kartfremstilte elementer: Ca, Co, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, Pb, Ti, V og Zn.

Bekkesedimenter (-0,18 mm). GF: 3 g bekkesediment ble løst i 5 ml varm  $\text{HNO}_3$  (7 N). Etter fortynning til 30 ml ble metallene bestemt med atomabsorpsjon. Kartfremstilte elementer: Co, Cr, Cu, Fe, Mn, Mo, Ni, Pb og Zn.

NGU: 1 g bekkesediment ble løst i 5 ml varm  $\text{HNO}_3$  (7 N). Etter fortynning 1:100 ble elementene bestemt med ICAP emisjonsspektrometer. Kartfremstilte elementer: Al, Ba, Ca, K, Mg, Na, Si, Sr, Ti og V.

Bekkevann ble analysert med 1) ICAP emisjonsspektrometer. Kartfremstilte elementer: Ba, Ca, Fe, Li, Mg, Mn, Na, Si og Sr. 2) Flammeløs atomabsorpsjon (grafittovn). Kartfremstilte elementer: Co, Cu, Mo, Ni, Pb og Zn.

Bekkemose og bekketory ble forasket ved  $480^\circ\text{C}$ . Asken ble analysert med røntgenfluorescens. Kartfremstilte elementer: Al, As, Ba, Ca, Co, Cr, Cu, Fe, K, Mg, Mn, Mo, Na, Ni, P, Pb, S, Th, Ti, U, V, W, Zn og Zr.

Gull ble bestemt i utvalgte prøver med flammeløs atomabsorpsjon etter oppslutning i kongevann og utfelling med Hg.

Uran ble bestemt i utvalgte vannprøver ved hjelp av laserindusert spektrometri.

#### Databehandling

Beregning av statistiske parametre samt faktor- og regresjonsanalyse ble gjort etter standardmetoder. Kart i M= 1:250 000 er tegnet med Calcomp-plotter. Kart i M= 1:1 mill. er tegnet med Calcomp-plotter, Applicon fargeplotter eventuelt Tektronix grafisk skjerm direkte i M= 1:1 mill eller nedfotografert fra kart i M= 1:250 000.

## RESULTATER

Forprosjektets resultater finnes bak i rapporten som:

- tabeller over statistiske parametre (Tabell 5-1 til 5-4)
- frekvensfordelingsdiagrammer (Figur 5-1 til 5-5)
- x-y plott for duplikatprøver (Figur 5-6 til 5-9)
- korrelasjonsmatriser (Tabell 5-7 til 5-8)
- faktorer fra faktoranalyse (Tabell 5-11)
- regresjonsligninger (tabell 5-9 til 5-10)
- kriegerte resultatkart i M=1:1 mill. (Figur 5-48 til 5-66)
- kart over flytende gjennomsnitt (Figur 5-10 til 5-47)
- symbolkart for enkeltverdier (Figur 5-67a til 5-67i)
- kart og tabeller over utskilte anomalier (Figur 5-68 til 5-79, Tabell 5-15 til 5-20)

Hovedresultatene kan oppsummeres slik:

- Kjente, regionale geologiske strukturer gir seg tilkjenne i de geokjemiske data. Eksempel: Fordeling av høye Ba-konsentrasjoner i bekkevann gir et mønster som i store trekk faller sammen med fjellranden (Figur 5-39).
- Noen regionale geokjemiske fordelinger indikerer mønstre som ikke umiddelbart lar seg forklare ut fra kjente geologiske forhold. Eksempel: Natrium i moreneprøver (Figur 5-14).
- De kjente mineralforekomster gir anomalier for flere elementer og i flere prøvetyper. Eksempel: Bidjovagge (koordinater J.11) og Tjärrostråket (koordinater I2-H4) (Tabell 5-15 til 5-20).
- Det er fremkommet geokjemiske anomalier der mineraliseringer fra før ikke er kjent. Eksempel: Porojärvi (koordinat F9) (Tabell 5-20, Figurene 5-68 til 5-72).
- Ialt 12 anomaliområder med meget sterke og overlappende anomalier lar seg skille ut (Tabell 5-20 og Figurene 5-68 til 5-72).

## DISKUSJON

Resultatkartene viser at den valgte prøvetetthet (ca. 3 prøver pr. 100 km<sup>2</sup>) er et brukbart kompromiss mellom de kryssende hensyn, stor arealdekning og tilstrekkelig detaljrikdom.

Det synes riktig å basere prøvetakningen på flere prøvetyper fordi:

- På noen prøvestasjoner mangler visse prøvetyper (Tabell 3-1). Sannsynligheten for å oppnå geokjemiske resultater fra ethvert prøvepunkt øker med antall prøvetyper.
- I mange tilfelle er det sterke korrelasjoner mellom anomalimønstre for ulike prøvetyper, slik at resultater for flere typer verifiserer hverandre og gjør tolkningen mer pålitelig (Tabell 5-15 til 5-20).
- I andre tilfelle gir ulike prøvetyper forskjellige regionale dispersjonsmønstre. Resultatene for de ulike prøvetyper kan derfor også utfylle og komplettere hverandre. Se for eks. Figurene 5-10 og 5-34 samt Tabell 5-13.
- Dispersjonsmekanismene er ufullstendig kjent og forskjellig i de ulike prøvemedier. Sammenligning av dispersjonsmønstre mellom elementer og media vil kunne øke forståelsen av de underliggende geokjemiske prosesser, se for eks. Figurene 5-11 og 5-35.
- Både i Finland, Norge og Sverige er det tidligere gjort geokjemisk prøvetakning innenfor visse deler av Nordkalotten. Imidlertid er de benyttede prøvetyper forskjellige. Ved å samle inn mange prøvetyper i Nordkalottprosjektet vil det gamle datamaterialet i alle land kunne anvendes ved tolking av de nye data.
- Ved så glissen prøvetakning som 1 prøve pr. 30 km<sup>2</sup> er transportomkostningene for å komme frem til prøvestasjonene store. Relative tilleggskostninger ved å ta flere prøvetyper blir stilsvarende små.

## KONKLUSJON OG REKOMMANDASJON

Geokjemisk kartlegging med 3 prøvestasjoner pr. 100 km<sup>2</sup> har avdekket regionale geokjemiske mønstre og lokale anomalier. Det anbefales derfor at hele Nordkalotten prøvetas med denne tetthet.

Det bør samles inn flest mulig prøvetyper på hver prøve-stasjon. Nedenfor nevnes 6 typer i prioritert rekkefølge. Herav utgjør de 3 første en minimumsversjon:

- 1 Bekkesedimenter
- 2 Bekketorv
- 3 Bekkemose
- 4 Morene
- 5 Humus
- 6 Bekkevann

Prøvene bør tas etter samme retningslinjer som i for-prosjektet og analyseres ved GF, NGU og SGU på flest mulig elementer etter de rutinemetoder institusjonene disponerer. Alle tre lands prøver av en type bør analyseres på samme laboratorium. Nærmere plan for analyse-ring bør avtales senere.

Resultatene bør fremstilles som enkelt-element kart, kombinerte kart og kart over filtrerte data samt mulige residualer i målestokker fra 1:250 000 til 1:2 mill. alt etter art og anvendelse. Videre databearbeiding bør gjøres av Nordkalottprosjektets datagruppe i samarbeid med de øvrige prosjekt-grupper.

Feltarbeidet bør gjennomføres over 2-3 år. Det er nødvendig med to år til bearbeiding og rapportering av resultater.

## KOSTNADER

Erfaringene fra forprosjektet viser følgende priser for prøvetakning (prisene er ikke uten videre sammenlignbare fordi budsjetttrutinene er ulike).

|                             |                              |
|-----------------------------|------------------------------|
| Finland (helikopter, moped) | 1750 Fmk/100 km <sup>2</sup> |
| Norge (helikopter, bil)     | 2800 Nkr/100 km <sup>2</sup> |

Kostnader for å dekke den finske del av Nordkalotten er estimert til Fmk 2 mill. Tilsvarende kostnader for den svenske delen er estimert til Sv.kr. 2 mill. (kostnadsnivå 1980/81).

Et overslag over prøvetakningskostnader for den norske del av Nordkalotten er gitt nedenfor (i 1980 N.kr.):

|                                  | 1981                   | 1982             | 1983           |
|----------------------------------|------------------------|------------------|----------------|
| Diett 4 NGU-medarbeidere         | 30 000                 | 60 000           | 40 000         |
| Lønn etc. engasjerte medarb.     | 190 000                | 360 000          | 220 000        |
| Bilhold                          | 50 000                 | 90 000           | 60 000         |
| Helikopterleie                   | <u>210 000</u>         | <u>390 000</u>   | <u>250 000</u> |
|                                  | 480 000                | 900 000          | 570 000        |
| Anslått prisstinging (10% pr.år) | <u>48 000</u>          | <u>100 000</u>   | <u>120 000</u> |
|                                  | <u>528 000</u>         | <u>1 000 000</u> | <u>690 000</u> |
| Total sum                        | <u>N.kr. 2.22 mill</u> |                  |                |

Etter de opplysninger som foreligger, er den finske og svenske finansiering i det alt vesentligste ordnet. For den norske del er det mulighet for en kombinert finansiering, ved delbevilgning over NGU's budsjett og andre poster på Statsbudsjettet.

## TABELLER

|            |                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Tabell 3-1 | Tilgjengelighet av de ulike prøvemedier uttrykt i prosent                                                                                   |
| Tabell 3-2 | Prøvepreparering utført på de ulike prøvemedier før kjemisk analyse                                                                         |
| Tabell 3-3 | Anvendte analyseteknikker og elementer kartfremstilt i de ulike prøvemedier                                                                 |
| Tabell 3-4 | Deteksjonsgrenser for de analyserte elementer i bekkesedimentprøvene                                                                        |

|    |     |     |
|----|-----|-----|
| Co | 0.4 | ppb |
| Cu | 1.1 | ppb |
| Mo | 0.3 | ppb |
| Ni | 0.6 | ppb |
| Pb | 0.2 | ppb |
| Zn | 1.0 | ppb |

x Som deteksjongrenser i plasmateknikk er brukt den konsentrasjon som gir et nettosignal lik 2 x standardavviket av bakgrunnsignalet (målt på blank). Som en praktisk nedre grense (limit of determination) er valgt å bruke 5 x deteksjongrensen.

AAS

Co, Ni, Mo, Zn, Cu, Pb: Halterna i de flesta prov ligger nära detektionsgränsen för metoden, vilket gör, att precisionen är låg och kan ej uppskattas för högre (optimi) haltnivåer (se Figur 5-7).
